

## PHYSICS EXAMINATION PROBLEMS SOLUTIONS AND HINTS FOR STUDENT SELF-STUDY

<b>Module Code and Lecturer</b>	PHY1106: AU and PV
<b>Name of module</b>	Oscillations section (PV)
<b>Date of examination</b>	June 2003

1. Notework / lectures: Look at expression for impedance of capacitor.  
 Freq. in denominator implies impedance is inversely proportional to freq. so as  
 freq. increases, the impedance decreases.

Notework / lecture derivation of LCR complex impedance.

Notework / lecture details about the phases etc.

Use standard equation for phase difference  $\phi$ : i.e.  $\tan \phi = \frac{\omega L - 1/\omega C}{R}$   
 (n.b. convert  $f$  to  $\omega$ )

Answer:  $\phi = 37^\circ = 0.65$  rads.

At resonance,  $\omega_0 = \frac{1}{\sqrt{LC}} = 63$  rads /s                      therefore  $f_0 = 10.1$  Hz

Expression for average power:  $P_{Av} = \frac{V_0^2}{2Z} \cos \phi$

which at resonance reduces to  $P_{Av} = \frac{V_0^2}{2R}$                       and gives  $P_{Av} = 289$  W

Use  $Q = \frac{\omega_0 L}{R}$                       which gives  $Q = 0.16$ .

2. Notework / lectures about balancing forces and the sum of individual forces etc. to give the forced damped harmonic oscillator equation.

For the picture; describe the: driving force; damping force, restoring force etc.

Notework / lectures derivation and proof as required for the complex value of  $A$ .

The phase term  $\phi$  will be zero under conditions of resonance. This occurs when:  $\omega_0 = \sqrt{\frac{k}{m}}$   
i.e. when  $\omega_0 = 5$  rads/s or when  $f_0 = 0.8$  Hz.

$$\text{Max. displ. (at resonance)} = \frac{F_0}{\omega b} \quad (\text{from given equation}) = 0.25 \text{ m.}$$

3. Clearly, amplitude remains unchanged, but a second block added:

so resonant frequency  $\omega_0 = \sqrt{\frac{k}{m}}$  and therefore  $\omega_0$  decreases by  $\sqrt{2}$ .

Max KE and PE stay unchanged (since  $E_{\text{total}} = \frac{1}{2} k A^2$ ).

Notework / lectures for this proof re. equation of motion solution.

First calculate the value of the spring constant  $k$ , using  $F = kx$  ( $= 50\text{N/m}$ ).

Then use standard equation  $\omega_0 = \sqrt{\frac{k}{m}}$  to give  $\omega_0 = 7.1$  rads /s or  $f = 1.13$  Hz.
