

# PHYSICS EXAMINATION PROBLEMS SOLUTIONS AND HINTS FOR STUDENT SELF-STUDY

<b>Module Code and Lecturer</b>	PHY1106: PV
<b>Name of module</b>	Waves and oscillations
<b>Date of examination</b>	June 2004

1. Differentiate expression for displacement to produce velocity.  $\dot{x} = \frac{F_0}{|Z_m|} e^{j(\omega t - \phi)}$

the real part comprises;  $\dot{x} = \frac{F_0}{|Z_m|} \cos(\omega t - \phi)$

The oscillator reaches velocity resonance when  $|Z_m|$  is a minimum (i.e. when  $\dot{x} = \sqrt{\frac{k}{m}}$  )

Max. velocity amp. at 4.9 rads / s or at frequency 0.78 Hz.

Use standard formula to calculate  $Q = 0.245$ .

2. Lecture note definition of phasor diagram and its use in representing phases.  
Write standard V-I relations for capacitor, resistor and inductor; then use these with integration or differentiation to produce standard lecture relation for the impedance of each component (including j-term to represent phase etc.)  
Add these impedance terms for series circuit situation to produce LCR circuit expression.  
Use standard concepts and definitions to produce the given expression (hint: draw an argand diagram to represent the angle, and the phasors represented by each component).

Use expression  $\omega = \frac{1}{\sqrt{LC}}$  to verify resonance condition.

Then use: at  $I_0 = \frac{V_0}{|Z|} = \frac{V_0}{R} = \frac{100}{20} = 5A$  resonance

Similar note-work to calculate  $P_{av} = 250 W$ .

3.i. Bookwork for definitions of phase velocity, group velocity and dispersion.

Use  $v_p = \frac{\omega}{k}$  and  $v_g = \frac{d\omega}{dk}$  to derive expressions ( $v_p = c + dk^2$  and  $v_g = c + 3dk^2$ )

ii. Amplitude unchanged; resonant freq. decreases by sq. root of 2; max KE and max PE unchanged.  
Standard bookwork (from lectures) to prove solution works for SHM.  
Start by calculating k (use  $F=kx$ ) = 50 N/m. Then use resonant freq. equation to show  $f = 1.13$  Hz.

4.  $\omega = 2\pi f = 62.8$  /s. Use  $v_p = \omega/k$  to calculate  $k = 6.28$  /m. Then  $\lambda = 2\pi/k$  to calculate  $\lambda = 1$  m.

Use lecture notes (and common maths understanding) to draw standard curves here.

Differentiate  $y = A \cos(\omega t - kx)$  and substitute into wave equation expression. The solution will then have

$$v_p = \sqrt{\frac{T}{\rho}}$$

5. Standard definition of stretched string impedance (in words and general equation).

Standard expression for impedance  $z$  in terms of  $T$  and  $\rho$ .

Use lecture notes or bookwork to derive the required relations for  $R$  and  $T$ .

The value of  $z_3$  enables complete destructive interference since the thickness is exactly a quarter wavelength (enlarge on this slightly with appropriate diagram).
